## NOTICE

When US Government drawings, specifications, or other data are used for any purpose other than a definitely related Government procurement operation, the Government thereby incurs no responsibility nor any obligation whatsoever, and the fact that the Government may have formulated, furnished, or in any way supplied the said drawings, specifications, or other data is not to be regarded by implication or otherwise, as in any manner licensing the holder or any other person or corporation, or conveying any rights or permission to manufacture, use, or sell any patented invention that may in any way be related thereto.

This final report was submitted by Personnel Research Division, Air Force Human Resources Laboratory, Lackland Air Force Base, Texas 78236, under project 7719, with Hq Air Force Human Resources Laboratory (AFSC), Brooks Air Force Base, Texas 78235. Dr. Nancy Guinn, Demographic and Attitudinal Research Branch, was the task scientist.

This report has been reviewed and cleared for open publication and/or public release by the appropriate Office of Information (OI) in accordance with AFIR 190-17 and DoDD 5230.9. There is no objection to unlimited distribution of this report to the public at large, or by DDC to the National Technical Information Service (NTIS).

This technical report has been reviewed and is approved.

LELAND D. BROKAW, Technical Director  
Personnel Research Division

Approved for publication.

HAROLD E. FISCHER, Colonel, USAF

20 ABSTRACT (Continue on reverse side if necessary and identify by block number) A sample of 15,252 basic airmen were administered the history opinion inventory (HOI) during basic military training. The service careers of these subjects were monitored for two years in order to assess the ability of the HOI to predict the criterion of in/out of service. An a priori adaptation index developed from HOI items correctly identified as high risk 23 percent of those subjects discharged from service during the two year period, while incorrectly labeling as high risk only 6 percent of those subjects still in service after two years. The possibility of increasing the accuracy of prediction by utilizing biographic/demographic data and the operational usefulness of the HOI are discussed.

## PREFACE

This research was conducted under Project 7719, Air Force Personnel System Development on Selection, Assignment, Evaluation, Quality Control, Retention, Promotion, and Utilization; Task 771902, Exploration of Methods for Increasing the Effectiveness of Personnel Programs.

Appreciation is expressed to Mr. Jim Friemann and A1C Vance Smith of the Computational Sciences Division, Air Force Human Resources Laboratory, for their professional and technical assistance in computer programming and accomplishment of desired analyses.

## SCREENING FOR ADAPTABILITY TO MILITARY SERVICE

### I. INTRODUCTION

Identification of personnel who are most likely to succeed on the job is the primary goal of every selection and classification program. Hiring personnel who will later terminate employment due to non-adaptability or unsuccessful performance represents a cost which might be minimized if more precise procedures could be developed to identify those individuals not likely to succeed at a later date. All branches of the armed services have been concerned with problems of adaptation. For over 15 years, research has been directed toward the development of a screening technique which could be used to identify recruits who are considered high-risk for problems in adaptation to the military environment (Flyer, 1959; Klieger, Dubuisson, & de Jung, 1961; Plag & Goffman, 1966). Some have investigated the efficiency of the psychiatric interview and general clinical assessment procedures in identifying potential maladaptive accessions (Jensen, 1961; Plag, 1964; Plag & Arthur, 1965; Plag, Arthur, & Phelan, 1970; Shoemaker, Drucker, & Kriner, 1974). Other investigators have focussed on the importance of pre-enlistment/biographical variables and their relationship to later performance and adjustment in the military (Flyer, 1959; Fischer, Ward, & Holdrege, 1960; Gordon & Bottenberg, 1962; Plag, 1962; Gunderson, 1963; Arthur, 1971). In several studies, various inventories developed for screening were evaluated for their effectiveness in predicting adjustment problems (Danielson & Clark, 1954; Jensen, 1961; Plag, 1962; Larson & Kristiansen, 1969; Bucky & Edwards, 1974; LaChar, Sparks, & Larson, 1974).

Although the practical usefulness of these personality and biographical/attitudinal inventories has not been conclusively demonstrated, findings from these studies do indicate consistent relationships between variables such as level of education, age, and general intellectual level with overall military effectiveness (Flyer, 1959, 1963, 1964; Plag & Hardacre, 1964; Drucker & Schwartz, 1973; Boyd & Jones, 1973). Other factors such as problems in schooling, family stability, and arrest history were also found to predict effective performance (Plag, 1962; Plag & Goffman, 1966; Plag, Arthur, & Goffman, 1970; Arthur, 1971).

In 1972, Air Force medical personnel initiated a research project to develop a screening technique which could be used to identify recruits who are considered high-risk for problems in adaptation to the military environment (LaChar, Larson, & Sparks, 1974). For use in this project, LaChar et al. developed a 100-item self-report history opinion inventory (HOI) designed to tap dimensions of school adjustment, family stability, social orientation, emotional stability, bodily complaints, motivation and expectations for achievement, and response toward authority.

Using the inventory and criterion data obtained on approximately 15,000 male airmen during basic training, two predictive scales were developed from the HOI for future use in screening. The prediction of emotional instability (PEI) scale was designed to measure characteristics associated with emotional maladjustment; the prediction of drug use admission (PDA) scale was designed to measure those characteristics associated with the acknowledgment of previous drug usage. These two scales were then combined into an adaptation index (ADI), and an optimal cutoff score was determined which would classify recruits into one of two categories, normal or high-risk. Based on this ADI cutoff score, 12 percent of the sample population was labeled as high-risk for military adaptation. According to records maintained by LaChar et al. half of the high-risk group did, in fact, experience problems in adjustment during basic training, although their problems did not necessarily result in discharge from service. This high-risk group was composed of seven percent of the normal criterion group, 41 percent of the severe adjustment group and 47 percent of the drug discharge group.

Based on these results, it was concluded that prediction of initial adaptability to military service is possible, and that such screening could result in substantial savings to the Air Force in identifying personnel who require special treatment or who should be separated from service (LaChar et al., 1974). However, the criterion classifications used in the initial analyses were partially based on subjective clinical and instructor evaluations of the individual's behavior. Prior to consideration of such an instrument for use in the operational screening of Air Force accessions, it was considered advisable that further investigation of the history opinion inventory be accomplished using the objective criterion of in-service versus actual separation/discharge from service.

### **Objectives of the Current Analyses**

The objectives of the current study were: (1) to follow up the assessments administered the history opinion inventory in basic military training in order to determine the accuracy of the HOI scores in predicting the criterion of in/out of service during the first two years after enlistment, and (2) to determine whether additional aptitudinal and biographical data might increase the effectiveness of the screening procedure.

### **B. METHOD**

**Subjects:** The sample population consisted of 15,252 basic airmen who were administered the HOI during basic military training at Lackland AFB, Texas, from June through August 1972.

**Procedure:** The data files established by LaChar et al. were matched with the airman tape files maintained by the Computational Sciences Division, Air Force Human Resources Laboratory, to obtain aptitudinal, biographical and discharge data. A total of 160 cases in the original population did not match the official data files, which reduced the sample population to 15,092. It is not believed that the loss of these cases represents any bias in the remaining sample which would materially affect the results obtained.

Discharge status was determined by a standard designation number (i.e., loss code) which identified all personnel who had been separated or discharged from service during the first two years after enlistment.

Loss codes indicating a similar reason for separation or discharge from service were grouped together as shown in Table 1. Based on the specific loss code indicated in an individual's official record, each individual in the sample population was assigned to one of the following mutually exclusive criterion groups:

1. *In-service* - this group consisted of 10,329 individuals who were still on active duty or had extended their original commitment as of September, 1974.
2. *Loss, normal separation* - this group of 658 included those individuals whose loss codes did not reflect any problem in adaptation, such as separation and transfer to AF Reserve.
3. *Loss, desirability indeterminate* - this group of 364 airmen included those categories of losses for personal/hardship reasons, death, release to enter an educational institution, and release for the convenience of the Government.
4. *Loss, physical reasons* - this group of 457 individuals included all separations/retirements due to physical disability, obesity, and failure to meet medical fitness standards at time of enlistment.
5. *Loss, unsuitability* - a total of 371 airmen comprised this classification of undesirable loss. Major reasons for discharge included character and behavior/personality disorders, drug abuse, and sexual deviation.
6. *Loss, marginal productivity* - this group of 853 airmen included discharges due to minimal or marginal productivity and unsuitability due to apathy, defective attitudes and inability to expend effort constructively.
7. *Loss, disqualified for retention* - this group of 1,828 individuals was discharged based on their failure to meet minimum requirements for retention in the Air Force.
8. *Loss, unfitness* - the 156 individuals in this group were discharged for reasons of unfitness or misconduct; i.e., frequent involvement in incidents of a discreditable nature with civil or military authorities, conviction by civil court/court martial, AWOL/desertion.
9. *Loss, miscellaneous undesirable* - the remaining 77 individuals assigned to this group included those released for reasons which were considered under a miscellaneous category of undesirable, e.g., being a conscientious objector or for the good of the service.

The nine loss categories were then combined to form three additional criterion classifications: out-of-service, loss-not undesirable, and loss-undesirable. The out-of-service group was comprised of all individuals separated or discharged from service regardless of cause. Individuals in the loss-not undesirable

group were those assigned to one of the three following loss categories: normal separations, loss-desirability indeterminate, or loss-physical reasons. The final group, loss-undesirable, included the loss categories of unsuitability, marginal productivity, disqualified for retention, unfitness, and miscellaneous-undesirable.

Scoring of the HOI response data and the cutoff scores used in the current study are those previously established by LaChar et al., 1974.

The actual items, scoring used in deriving the HOI scale scores, and estimates of scale reliability are presented in Tables A1 and A2 in Appendix A. The weighted linear combination of the two scales used to derive the adaptation index was .6568 of the PEI scale value and .7541 of the PDA scale value. The decision rules (cutoff scores) based on the optimum value which differentiated between recruits who would and would not have problems in basic training were as follows: PEI = 7.5 scale value; PDA = 11.5 scale value; ADI = 12.5 scale value.

Distributional analyses of HOI scale scores were accomplished to determine the number of individuals scoring at each score interval on the three scales. Based on cutoff scores for the HOI scales, the percentage of individuals in each criterion group identified as high-risk for problems in adaptation was tabulated.

Comparisons between the means of the in-service group and the different loss groups were accomplished, and the differences between means were tested for statistical significance by means of t-tests. Error rate for these comparisons was controlled per hypothesis; i.e., a total Type I error rate of .05 was considered acceptable.

Correlations were also computed to indicate the relationships between HOI scores and the various in/out criterion categories. Finally, regression analyses were accomplished to determine the usefulness of biographical and aptitudinal data in predicting adaptability to military service, and whether these data significantly increase accuracy in prediction over and above the use of the HOI scores alone.

### III. RESULTS AND DISCUSSION

The means and standard deviations of the HOI scores by criterion classification are presented in Table 2. Results of the t-tests between the means of the in-service group and the loss groups, summarized in Table 3, indicate the differences between the means are quite similar for the three scales. In a majority of comparisons, the in-service group mean differs significantly from the loss/out-of-service means on all scales. However, mean comparisons between in-service and normal separations and between in-service and loss-desirability indeterminate were not significant across all scales. For the PEI scale, comparisons of mean differences between the in-service group and the unfitness and miscellaneous-undesirable groups were also non-significant.

*Table 2. Means and Standard Deviations of Scale/Index Scores - Original Sample*

Criterion Group	Valid N	PEI Scale		PDA Scale		Adaptation Index	
		Mean	SD	Mean	SD	Mean	SD
In Service	10,329	3.03	2.42	5.20	3.46	5.91	3.80
Out of Service	4,764	4.16	3.51	7.46	5.25	8.35	5.93
Loss, Not Undesirable	1,479	3.35	2.98	5.56	4.14	6.39	4.78
Normal separation	658	3.15	2.60	5.33	3.56	6.09	4.03
Desirability Indeterminate	364	3.14	2.83	5.40	3.81	6.13	4.41
Physical Reasons	457	3.80	3.52	6.03	5.04	7.04	5.83
Loss, Undesirable	3,285	4.53	3.67	8.32	5.47	9.24	6.18
Unsuitability	371	4.05	2.95	7.37	4.09	8.22	4.55
Marginal Productivity	853	3.30	2.66	7.05	4.07	7.48	4.40
Disqualified - Retention Stds	1,828	5.37	4.08	9.25	6.21	10.50	7.02
Unfitness	156	3.19	2.47	7.15	3.81	7.49	4.11
Miscellaneous - Undesirable	77	3.10	2.32	7.17	4.54	7.44	4.55

*Table 3. Results of t-Tests Between In-Service and Loss Category Means – Original Sample*

Mean Comparisons	t-ratio		
	PEI	PDA	ADI
In/out of service	23.00**	31.35**	30.43**
In/loss, not undesirable	4.62**	3.62**	4.39**
In/loss, normal separations	1.26 <sup>a</sup>	.88 <sup>a</sup>	1.12 <sup>a</sup>
In/loss, desirability indetm	.85 <sup>a</sup>	1.05 <sup>a</sup>	1.07 <sup>a</sup>

In/loss, unfitness	.84 <sup>a</sup>	6.98**	5.14**
In/loss, misc undesirable	.28 <sup>a</sup>	4.95**	3.52**

<sup>a</sup>Not significant.

\*Significant at .05 level.

\*\*Significant at .01 level.

The correlations of the HOI scales for the various criterion group classifications are presented in Table 4. Those undesirable categories containing a sufficient number of individuals to assure some stability of results were used separately to indicate the effectiveness of the scales in differentiating between those in-service and those discharged for a specific reason. All correlations are statistically significant at or beyond the .01 level. The absolute value of the correlations reported may be somewhat inflated since a portion of the sample had been previously used for scale construction. However, the degree of inflation can be considered minimal based on the large sample size and the fact that the present criterion groups were not used in the actual scale development. Although significant, the observed relationship between HOI scores and the criterion groups comprising the marginal producers or unsuitable personnel appears negligible from a practical standpoint. A definite but low to moderate relationship is evident for the remaining criterion groups. It should also be noted that the correlations obtained on a sample population previously screened by operational selection tests are somewhat lower than if they had been computed on an unrestricted population.

*Table 4. Zero Order Correlations<sup>a</sup> – Original Sample*

Criterion Groups	HOI Scores		
	PEI	PDA	ADI
In/out	.2022	.2735	.2659
In/total loss, undesirable	.2241	.3122	.3013
In/loss, marginal productivity	.0296	.1378	.1072
In/loss, disqualified for retention	.2910	.3387	.3448
In/loss, unsuitability	.0763	.1131	.1093

<sup>a</sup>All correlations significant at .01 level.

The statistical significance of a measure often fails to reflect the practical usefulness of any screening device. An assessment of HOI utility can be made by a comparison of the number of personnel correctly identified (i.e., hits) versus the number of individuals incorrectly classified (i.e., false positives and misses). Hits include all personnel identified as normal who are still in service and those identified as high-risk who have been discharged from service. False positives include those individuals still in service who were identified by the HOI as high-risk and misses include those losses classified as normal. Table 5 shows the frequency and percent of each criterion group identified as normal or high-risk using the decision rules established by LaChar in 1974. Cumulative percentage distributions indicating the number of individuals at each score interval for the three HOI scales are also presented in Tables A3 through A5 in Appendix A. Overall, 11 percent of the total sample used in these analyses was identified as high-risk by the PDA and ADI scales; nine percent by the PEI scale. Six percent of the in-service group was identified as high-risk by each of the three decision rules for the HOI scales. The scales vary somewhat in the percentage of the loss categories identified as high-risk. Using the PEI scale, 18 percent of all losses and 21 percent of the undesirable losses were identified as high-risk; with the PDA scale, 22 percent of all losses, 28 percent of the undesirable losses; with the ADI index, 23 percent of all losses, 28 percent of the undesirable category. A closer review of the high-risk subgroup identified by the PDA or ADI scales shows that over 60 percent were actually discharged from service and over 55 percent for reasons of undesirability (Table 6). It appears that the PDA is almost as effective as the ADI index in identifying personnel who are separated or discharged from service. If similar results are found in future validation of the HOI, consideration should be given to simplifying the scoring process by using a single scale score for screening instead of the weighted ADI index.

Since the sample population entered service, enlistment standards have become more stringent. Today's accessions must meet three criteria: (1) each individual must obtain a total score of 170 or higher on the four combined aptitude indexes of the Armed Services Vocational Aptitude Battery; (2) their General Aptitude Index score must be 45 or higher; and (3) if they receive a mental classification of Category III or IV on the Armed Forces Qualifying Test, they must be a high school graduate. To give some insight into the effectiveness of the personality scales of the HOI on a population similar to current enlisted accessions, identical analyses on only those recruits meeting the new enlistment standards were performed. The actual number in each category qualifying on the multiple standards is shown in Table 7.

Descriptive statistics for the HOI scales on this restricted population are presented in Table 8 with the results of the comparisons between the means in Table 9. Results of the analysis of differences between the means between in-service personnel and out-of-service categories were similar to those in the original sample. Statistical comparisons of PEI mean differences between in-service personnel and each of the loss categories reflected significant differences in all comparisons except those involving normal separations, losses with desirability indeterminate, marginal productivity, unfitness and miscellaneous-undesirable losses. For PDA and ADI mean comparisons, differences between in-service personnel and two of the loss groups, normal separations and losses-desirability indeterminate were not significant. In addition, the in-service ADI mean did not differ significantly from the miscellaneous-undesirable losses. All other comparisons of means on the three scales were significant at or beyond the .05 level.

Some decrease in the absolute magnitude of the correlations between HOI scores and criterion categories is also evident in the restricted population (Table 10). Although the observable relationships are attenuated by the restriction of range imposed by the new enlistment criteria, the low to moderate correlations are still statistically significant.

The proportion of individuals identified as high-risk by the decision rules of the HOI scales differ slightly from the original sample as shown in Table 11. The more detailed frequency and cumulative percentage distributions are contained in Tables A6 through A8 in Appendix A. Due to the more stringent selection standards, only 26 percent of the undesirable loss category was identified as high-risk compared to 28 percent in the original sample. However, it should be noted that 35 percent of the undesirable loss category would have been rejected prior to enlistment had the new criteria been prerequisite for entry into the Air Force in 1972. Of the number identified as high-risk by the PDA or ADI scale, over 50 percent were actually discharged for reasons of undesirability (Table 12).

Since certain biographical and aptitudinal data are available from an individual's official records at the time of entry into the Air Force, the use of these data would eliminate the administration of the HOI if such data were as effective as the HOI scales in identifying personnel who are discharged from service.

*Table 5. Frequency and Percent of Original Sample in Each Criterion Group by Scale/Index Cutoff Scores as Normal or High Risk*

Criterion Group	PEI Scale				PDA Scale				ADI Index			
	Normal <7.5		High Risk ≥7.5		Normal <11.5		High Risk ≥11.5		Normal <12.5		High Risk ≥12.5

Therefore, a series of regression analyses were accomplished on the original and current enlistment standards samples to determine the usefulness of biographical and aptitudinal data alone or in combination with the HOI scales in predicting loss from active duty. Based on the similar percentage of out-of-service and undesirable loss personnel identified by the PDA scale in comparison to the PEI scale and the weighted ADI index, another series of analyses were accomplished to see if any significant loss in predictive accuracy would occur by using the PDA scale alone. Two criterion groupings were used for the regression analyses: in-service and out-of-service; in-service and total loss-undesirable. Multiple correlations for the various groups of predictors are given in Table 13. Summaries of these regression analyses are presented in Tables 14 and 15. The first regression comparison indicates that the aptitudinal and biographical data do add significantly to prediction over above the ADI index. On the other hand, however, the aptitudinal and biographical data cannot be used in lieu of the ADI scale; i.e., the ADI index does make a unique contribution in both criterion groupings. The comparison to determine whether the PDA scale contributes

**Table 13. Multiple Correlations<sup>a</sup>**

as much as the combination of all HOI scales indicates the PDA scale can be effectively used alone. If the predictive efficiency of the PDA scale over the other HOI measures is found in future validation studies, the continued use of the PEI scale to form the weighted ADI index appears redundant and unnecessarily more complicated than a single score cutoff. The final comparison of squared multiple correlations was made to determine if the aptitudinal and biographical data still made a significant and unique contribution if the PDA scale were used alone. Results of this comparison indicate the aptitudinal and biographical data make a significant contribution to the PDA scale also.

In general, the value of implementing any screening procedure based on biographical, aptitudinal, or personality data must be carefully evaluated by considering the savings which would be accrued by early identification of maladaptive personnel versus the loss to the Air Force of potentially successful personnel who might be denied enlistment or separated prematurely from service. When the quantity and quality of the prospective recruit manpower pool are high, a coarse screening methodology can be cost-effective in saving the expenses of training, counseling, treatment, and administration associated with personnel who have adjustment problems even though it also identifies a sizeable proportion of potentially productive personnel. On the other hand, if the volume of prospective recruits is low, the number of potentially successful personnel identified as maladaptive becomes a critical issue.

Should a screening measure such as the HOI be considered for operational use, several additional procedures should be incorporated to safeguard against identifying and possibly rejecting a large number of potentially productive and successful military personnel. For example, counseling could be scheduled for all personnel exhibiting symptoms of initial maladjustment. Many problems might be transitory if professional guidance were made available during basic training. Secondly, additional in-depth assessment procedures should also be administered to high-risk personnel in an effort to identify those with major psychiatric/emotional problems who should be separated from service as soon as possible.

#### IV. CONCLUSIONS AND RECOMMENDATIONS

The correlations obtained for the HOI scales appear to indicate that the self-report data contained in the HOI has some practical usefulness as a rough, preliminary screening device. However, the small magnitude of the observed relationships necessitates careful review by professional personnel of all personnel identified as high-risk. In no instance should identification as high-risk by the HOI be used as the sole basis for any adverse personnel action. On the positive side, the HOI does identify a sizeable proportion of recruits who were actually discharged from service as undesirable during the first two years of active duty. Even under current enlistment standards, over 25 percent of the undesirable losses would have been labeled as high-risk. However, the overall savings which might be accrued from early identification of the high-risk group might be obscured by the costs of implementing a secondary assessment and counseling phase which is considered necessary with the use of a rough screening device such as the HOI.

Prior to the use of the HOI in an operational setting, the following recommended courses of action are considered mandatory.

- a. Revalidate the HOI on accessions under current enlistment standards to determine its effectiveness and stability on a new population. In the original sample, a large number of personnel who were discharged for admission to prior drug usage were used for scale construction. Although the PDA scale appears to be quite effective in identifying all types of undesirable losses, the appropriateness of the original scales or cutoff scores developed on that population may be questionable if a decrease in the number of drug discharges has occurred during the past two years.
- b. While results obtained on the original sample suggest that such a screening procedure might be used effectively, the population consisted of male accessions only. Prior to using the HOI as a screening device on a female population, additional research must be accomplished to establish the applicability of the scales and cutting scores on a WAF population.
- c. It is further recommended that use of this screening device should be limited to preliminary screening only and that additional psychometric and/or psychiatric assessment be mandatory before any personnel action is recommended. Every effort should be made to retain as many of the potentially successful personnel in the high-risk category as possible.

d. To simplify the administrative scoring of the HOI, it is recommended that further research on this instrument investigate the possibility of developing one scale rather than the complex weighting process used for deriving the ADI index score.

e. Based on the preliminary regression analyses, additional aptitudinal and biographical data which is available on all recruits should be considered in combination with HOI data to improve the accuracy in identification of maladaptive personnel.
